In the article there is proved the possibility of using ortho-phosphoric acid with special emulsifiers instead of hydrochloric acid – for the production of road cationic slow-setting bitumen emulsions. There is ascertained the difference between used for bitumen emulsions distilled binder (Nybit E85 bitumen), produced from heavy crude oil, and oxidized bitumens (grade 70/100 bitumen produced by JSC Mozyr Refinery and grade BND 60/90 bitumen of JSC UkrTatNafta), produced from light crude oil. The difference is analyzed between physical-mechanical indices of distilled and oxidized bitumens. Eight bitumen emulsion formulations were developed based on usage hydrochloric acid, three bitumens and three emulsifiers (Redicote E-11, Redicote 404 and Redicote E-4875), as well as four formulations based on usage of ortho-phosphoric acid, two bitumens and two emulsifiers (Redicote EM44 and Redicote C-320). There was investigated the influence of hydrochloric and ortho-phosphoric acids upon the physical-technical indices of road cationic slow-setting bitumen emulsions and the difference was ascertained between the indices of bitumen emulsions based on distilled and oxidized bitumens. Bitumen emulsion formulations were developed based on usage of ortho-phosphoric acid and special emulsifiers for the class of cationic slow-setting emulsions for slurry seal and microsurfacing mixtures.

Keywords: bitumen emulsion, hydrochloric and ortho-phosphoric acids, slurry seal and microsurfacing mixtures

1. Introduction

Bitumen emulsions found the broad-range usage in the road construction world-wide. The application of bitumen in a form of emulsion have a number of advantages: application of organic binding materials in a form of emulsion allows decreasing bitumen consumption for 20÷30% w/w due to formation of...
thinner bitumen film around the grains of mineral materials; absence of necessity for emulsion and aggregate pre-heating allows saving fuel-power resources; extension of road season due to road works performance at the temperature not less than 5°C; possibility of wet aggregate treatment and road works performance with wet base; emulsions storage is simple and does not require warehouses with complicated heating system. It is extremely important that emulsions allow working at as unfavorable weather conditions, as making impossible (even in presence of surfactants) to reach the necessary quality of works with application of hot mixes. It is possible to use road emulsions as a binder for plenty of road technologies. In spray applications the emulsion is used for surface dressing (chip seal), fog seal, scrub seal, graded aggregate seal, tack coat, prime coat, penetration macadam and dust control. In mix applications it is used for slurry seal, microsurfacing, cape seal, open-graded cold mix, dense-graded cold mix, soil stabilization, pre-coated chips, stockpile mix and RAP [1–2]. The results of theoretical investigations and practical application of bitumen emulsions have shown that the greatest effect is reached with cationic bitumen emulsions applied.

2. Analysis of recent investigations and publications

A lot of investigations were done on application and modification of cationic bitumen emulsions, both world-wise [3–6] and in the Ukraine in particular [7–8]. Still, the review of scientist’s publications, both the domestic and foreign ones, has shown that the issues of application of this or that acid in an emulsion are cleared-up insufficiently. It is known that for the production of cationic bitumen emulsion it is possible to use hydrochloric, ortho-phosphoric and acetic acids. Let us address out attention to the first two ones – as the most used in production. In Ukraine there is widely used hydrochloric acid for emulsions – due to the worked-up technology of its application. (Though in the world-scale the usage of ortho-phosphoric acid is not a problem). Let us try to compare these acids. Hydrochloric acid is rather aggressive and highly corrosive, while that may lead to destruction of technological equipment. The labor safety during the working process shall be on the raised level. Besides, in the Ukraine it is required that acid implies getting license for work with precursors. Therefore, the usage of hydrochloric acid not just leads to increase of cost of technology, but also requires a whole chain of additional technological modifications, both that of the personnel’s working place itself, and of the production equipment – at installation stage and in course of its operation.

Significant contribute into investigation of the problem of acid usage for emulsions was made by A. James [9–10]. He asserts that alternative acids can provide for advantages in operation indices at the stage of final application of emulsion. Reaction of acid with aggregate, along with resulting changes of pH make significant influence upon the cationic emulsions breakage. Besides, the
Acids in Bitumen Emulsions

Acids in Bitumen Emulsions

choice of acid makes influence upon the process, while the products received will potentially make influence upon the adhesion and rheology of the residual [11]. A. James together with T. Ng analyzed the usage of ortho-phosphoric acid for slurry seal and microsurfacing technologies and determined the peculiarities and advantages of application of this acid for the said technologies [12–13].

The purpose of this work is determination of the efficiency of ortho-phosphoric acid application for production of slow-setting cationic bitumen emulsions (based on the accessible materials), as well as determination of its influence on the emulsion quality.

3. Main part

For the production of bitumen emulsions based on hydrochloric and ortho-phosphoric acids there were taken popular in Ukraine raw materials, namely: oil distilled-bitumen grade Nybit Е85 produced by Nynas (Sweden), oil viscous oxidized road bitumen grade 70/100 produced by JSC Mozyr Refinery (Belarus Republic), oil viscous oxidized road bitumen grade BND 60/90 JSC UkrTatNafta (Ukraine), emulsifiers Redicote E-11, Redicote 404, Redicote E-4875NPF, Redicote EM44 and Redicote C-320 produced by AkzoNobel (Sweden).

Physical-mechanical properties of bitumens are presented in Table 1. Penetration (Pen) and Ductility (D) were determined at 25 °C.

According to Table 1, the difference between the oxidized bitumens and the distilled ones consists in the fact that the first ones have the larger plasticity interval (Softening Point is higher, while Fraaß breaking point is lower). For their part, distilled bitumens have substantially lower paraffin content and perceptibly higher total acid no., while that can be explained by differences in crude-oil and its processing technology.

Production of bitumen emulsions was done on Danish laboratory batch bitumen-emulsion plant type DenimoTech SEP-0,3R (figure 1). Bitumen
emulsion formulations were developed for getting cationic slow-setting emulsions (CSS) intended for usage in slurry seal and microsurfacing technologies. Formulations with hydrochloric acid are presented in Table 2, while with ortho-phosphoric acid – in Table 3.

According to recommendations [12-13], production of efficient emulsions for slurry seal and microsurfacing technologies is possible not only based on high-acidic bitumen (in our case Nybit Е85), but also on low-acidic one – with application of special emulsifiers. As those latter ones, there were taken the recommended by AkzoNobel emulsifiers – Redicote EM44 and Redicote C-320. These two emulsifiers are intended for rapid-setting emulsions, but in combination with ortho-phosphoric acid they provide for getting high-quality slow-setting emulsions.

Physical-mechanical indices of bitumen emulsions based on hydrochloric acid are presented in Table 4, while based on ortho-phosphoric acid – in Table 5.

All the bitumen emulsions produced correspond to [14] for the grade ECS-60 (emulsion cationic road slow-setting with bitumen content from 58 to 62%) and can be applied for slurry seal and microsurfacing technologies.

From Table 4 one can see not large difference between the values of breaking index and pH of bitumen emulsions on distilled and oxidized bitumens with hydrochloric acid. Due to higher total acid number of distilled bitumens these indices of bitumen emulsions on Nybit E85 bitumen are lower than in emulsions on oxidized bitumens.
The main difference in physical-technical indices of emulsions on hydrochloric and ortho-phosphoric acids consists in the lower values of breaking index and emulsion pH, while it means higher reactivity of this emulsion. The worse indices of stability during storage mean (in emulsions on ortho-phosphoric acid) the possibility of worse bitumen emulsification during the emulsion production, i.e.: there is possibility of rapid emulsification of bitumen droplets after milling by colloid mill, while due to this phenomenon the droplets are from the very beginning larger than in the systems on hydrochloric acid. Besides, in course of testing on miscibility with mixtures of grained composition and breaking index there was noticed the increased stickiness and darker coloring of mixes on ortho-phosphoric acid – in comparison with the systems on hydrochloric acid. In general, based on the testing done, it is possible to confirm the efficiency of using ortho-phosphoric acid for production of slow-setting cationic bitumen emulsions.

4. Conclusion

1. There was ascertained the difference of physical-mechanical indices of distilled and oxidized bitumens.
2. There were developed formulations of bitumen emulsions on distilled and oxidized bitumens based on usage of hydrochloric and ortho-phosphoric acids and special emulsifiers.
3. There was determined difference between physical-technical indices of emulsions on different acids.
4. There was proved that the usage of ortho-phosphoric acid and special emulsifiers provides for production of cationic slow-setting emulsions for slurry seal and microsurfacing mixtures.
