Close-to-convexity properties of basic hypergeometric functions using their Taylor coefficients

K. Raghavendar and A. Swaminathan

Abstract: In this paper, we find the conditions on parameters $a$, $b$, $c$ and $q$ such that the basic hypergeometric function $z\phi(a, b; c, q, z)$ and its $q$-Alexander transform are close-to-convex (and hence univalent) in the unit disc $D := \{ z : |z| < 1 \}$.

AMS Subject Classification: 30C45, 33C05, 33D05, 33D15
Key Words and Phrases: Basic hypergeometric functions, Gaussian hypergeometric functions, close-to-convex functions, starlike functions, convex functions

1 Introduction and Notation

Most of the mathematical functions which are encountered in numerous contexts are of hypergeometric type. The ordinary or Gaussian hypergeometric function $2F_1(a, b; c; z)$ is defined by the series

$$2F_1(a, b; c; z) = \sum_{n=0}^{\infty} \frac{(a, n)(b, n)}{(c, n)n!} z^n, \quad |z| < 1,$$

where $a$, $b$, $c$ are complex numbers such that $c \neq 0, -1, -2, -3, \ldots$, $(a, 0) = 1$ for $a \neq 0$ and

$$(a, n+1) = (a+n)(a, n), \quad n = 0, 1, 2, \cdots.$$

In the exceptional case $c = -p$, $p = 0, 1, 2, \cdots$, $F(a, b; c; z)$ is defined if $a = -m$ or $b = -m$, where $m = 0, 1, 2, \cdots$ and $m \leq p$. Heine (see [1, 5]) defined ‘$q$-analogue’ or ‘basic analogue’ of Gaussian hypergeometric function in the following way

$$2\Phi_1(a, b; c; q; z) = 1 + \frac{(1-q^a)(1-q^b)}{(1-q^c)(1-q)} z + \frac{(1-q^a)(1-q^{a+1})(1-q^b)(1-q^{b+1})}{(1-q^c)(1-q^{c+1})(1-q)(1-q^2)} z^2 + \cdots,$$

where $|q| < 1$. For the base $q$, $0 < q < 1$, define

$$(a; q) = \frac{1 - q^a}{1 - q}, \quad (0; q) = 1.$$

Clearly, by $L$'-Hospitals’ rule, we have

$$(a; q) \to a \text{ as } q \to 1,$$

and the basic factorial notation is

$$(a; q)! = (1; q)(2; q) \cdots (n; q).$$

Now we write

$$(1 - q^a)(1 - q^{a+1}) \cdots (1 - q^{a+n-1}) = (a; q)(a + 1; q) \cdots (a + n - 1; q)(1 - q)^n$$

$$= (a; q)_n(1 - q)^n, \text{ say,}$$

and thus in the limiting case $q \to 1$, we have

$$\lim_{q \to 1} (a; q)_n = \lim_{q \to 1} \prod_{j=1}^{n} \frac{1 - q^{a+j-1}}{(1 - q)^n} = (a, n).$$

With this observation, the Heine’s series or the $q$-analogue of Gauss function defined above takes the following form [17]:

$$2\Phi_1(a, b; c; q; z) = \sum_{n=0}^{\infty} \frac{(a; q)_n(b; q)_n}{(c; q)_n(q; q)_n} z^n, \quad |z| < 1.$$  

We remark that in the limiting case $q \to 1$, the function $2\Phi_1(a, b; c; q; z)$ reduces to $2F_1(a, b; c; z)$.

The geometric properties of $2F_1(a, b; c; z)$ for various values of $a$, $b$ and $c$ are well known. For details, we refer to [7, 9, 10, 13, 14] and references therein. Similar study about $2\phi_1(a, b; c; q; z)$ is not available in the literature, except [6, 15, 16]. Hence the main objective of this work is to find the geometric properties of $2\phi_1(a, b; c; q; z)$ from the parameters $a$, $b$ and $c$ for $0 < q < 1$. For this purpose the $q$-Gamma function $\Gamma_q(x)$ [2], which is the $q$-generalization of the Gamma function and defined by

$$\Gamma_q(x) = \frac{(q; q)_{\infty}}{(q^x; q)_{\infty}} (1 - q)^{1-x}, \quad 0 < q < 1,$$

is used.

Throughout the sequel, we always assume that $z \in \mathbb{D}$ where $\mathbb{D}$ is the unit disc given by $\{z : |z| < 1\}$. The class of normalized analytic functions

$$\mathcal{A} = \left\{ f : \mathbb{D} \to \mathbb{C} \mid f(z) = z + \sum_{n=2}^{\infty} A_n z^n \right\}$$  

(1.1)
Close-to-convexity properties of basic hypergeometric ... 

has been studied extensively, together with its subclass of univalent (schlicht) functions

\[ S = \{ f \in A \mid f \text{ is one-to-one in } \mathbb{D} \}. \]  

(1.2)

For \( f \in A \), the \( q \)-difference operator of the basic differentiation is given by

\[ (D_q f)(z) = \begin{cases} 
  \frac{f(z) - f(qz)}{z(1-q)}, & z \neq 0 \\
  f'(0), & z = 0.
\end{cases} \]

Clearly \( D_q \to \frac{d}{dz} \) as \( q \to 1 \). A function \( f \in A \) is called starlike \((f \in S^*)\) if

\[ \text{Re} \left( \frac{zf'(z)}{f(z)} \right) > 0, \quad z \in \mathbb{D} \]  

(1.3)

and \( f \in A \) is called close-to-convex \((f \in K)\) if there exists \( g \in S^* \) such that

\[ \text{Re} \left( \frac{zf'(z)}{g(z)} \right) > 0, \quad z \in \mathbb{D}. \]  

(1.4)

Using \( q \)-difference operator the authors in [6] generalize the family \( S^* \) as follows:

**Definition 1.1.** A function \( f \in A \) is said to belong to the class \( \mathcal{P}S_q \) if

\[ \left| \frac{z(D_q f)(z)}{f(z)} \right| - \frac{1}{1-q} \leq 0, \quad z \in \mathbb{D}. \]  

(1.5)

Clearly \( \mathcal{P}S_q \) reduces to \( S^* \) as \( q \to 1^- \). Not much is known about the class \( \mathcal{P}S_q \), except what is discussed in [6] for the inclusion of the functions \( \Phi_1(a, b; c; q; z) \) and for the study of certain continued fraction expansions given by [11]. Recently the second author, among other results, studied [15, 16] certain continued fraction expansion for \( \Phi_1(a, b; c; q; z) \) and used it to improve the results given in [6]. We now generalize the class \( K \) in the spirit as the Definition 1.1 generalizes \( S^* \).

**Definition 1.2.** A function \( f \in A \) is said to belong to the class \( \mathcal{P}K_q \) if there exists \( g \in S^* \) such that

\[ \left| \frac{z(D_q f)(z)}{g(z)} \right| - \frac{1}{1-q} \leq 0, \quad z \in \mathbb{D}. \]  

(1.6)

We observe that (1.6) reduces to (1.4) as \( q \to 1^- \) and hence in the limiting case \( \mathcal{P}K_q \) reduces to \( K \). Particular choice of the function \( g \) used in the study of \( \mathcal{P}K_q \) are interesting. According to Frideman [4], there exists only nine functions of the class \( S \) whose coefficients are rational integers. They are

\[ \frac{z}{1 \pm z}, \quad \frac{z}{1 \pm z^2}, \quad \frac{z}{(1 \pm z)^2}, \quad \frac{z}{1 \pm z + z^2} \]  

(1.7)
together with the identity function. It is easy to see that each of these functions maps the disc \( \mathbb{D} \) onto a starlike domain and the last fact is easy to see from the analytic characterization given by (1.3). We remark that each of these functions plays an important role in function theory since these together with its rotation are extremal for interesting subfamilies of \( S \). We first state few useful criteria for a normalized power series \((A_0 = 0, A_1 = 1, )\) defined by

\[
f(z) = \sum_{n=0}^{\infty} A_n z^n, \quad B_n = \frac{(1 - q^n)A_n}{1 - q},
\]

(1.8) to belong to \( \mathcal{P} K_q \).

**Lemma 1.1.** Let \( f \) be defined by (1.8) and \( B_n = \frac{(1 - q^n)A_n}{1 - q} \). Then we have the following:

1. \( \sum_{n=1}^{\infty} |B_{n+1} - B_n| \leq 1 \) implies \( f \in \mathcal{P} K_q \) with \( g(z) = z/(1 - z) \).

2. \( \sum_{n=1}^{\infty} |B_{n-1} - B_n + B_{n+1}| \leq 1 \) implies \( f \in \mathcal{P} K_q \) with \( g(z) = z/(1 - z + z^2) \).

3. \( \sum_{n=1}^{\infty} |B_{n-1} - 2B_n + B_{n+1}| \leq 1 \) implies \( f \in \mathcal{P} K_q \) with \( g(z) = z/(1 - z^2) \).

4. \( \sum_{n=1}^{\infty} |B_{n-1} - B_{n+1}| \leq 1 \) implies \( f \in \mathcal{P} K_q \) with \( g(z) = z/(1 - z^2) \).

**Proof.** (1) Suppose that \( \sum_{n=1}^{\infty} |B_{n+1} - B_n| \leq 1 \).

The power series converges for \( |z| < 1 \). Since

\[
|B_n| = \left| \sum_{k=1}^{n-1} (B_k - B_{k+1}) - 1 \right| \leq \sum_{k=1}^{n-1} |B_k - B_{k+1}| + 1 \\
\leq \sum_{k=1}^{\infty} |B_k - B_{k+1}| + 1 \leq 2
\]

and

\[
|B_n| = \left| \frac{(1 - q^n)A_n}{1 - q} \right| \leq 2,
\]

(1.9)

we have

\[
|A_n| \leq \frac{2}{1 + q + \cdots + q^{n-1}}.
\]
Thus, by applying Root test, the radius of convergence of $f(z)$ is seen to be unity and so $f$ is analytic in $\mathbb{D}$. Next we show that $f$ belongs to $\mathcal{PK}_q$ with respect to the starlike function $g(z) = z/(1 - z)$. For this we need to show that $f$ satisfies the condition

$$
(1 - z)(D_q f)(z) - \frac{1}{1 - q} \leq \frac{1}{1 - q}, \quad z \in \mathbb{D}.
$$

By (1.8) and the definition of $q$-difference operator, the above inequality can be rewritten in the equivalent form

$$
T_q := \frac{1}{1 - q} - \left| 1 + \sum_{n=1}^{\infty} (B_{n+1} - B_n) z^n - \frac{1}{1 - q} \right| \geq 0.
$$

Applying triangle inequality, we find that

$$
T_q \geq \frac{1}{1 - q} - \left| 1 - \frac{1}{1 - q} \right| - \left| \sum_{n=1}^{\infty} (B_{n+1} - B_n) z^n \right|
\geq \frac{1}{1 - q} - \frac{q}{1 - q} - \sum_{n=1}^{\infty} |B_{n+1} - B_n||z|^n
\geq 1 - \sum_{n=1}^{\infty} |B_{n+1} - B_n| \geq 0, \quad \text{by hypothesis.}
$$

Thus (1.10) holds for all $z \in \mathbb{D}$. Hence $f \in \mathcal{PK}_q$ with respect to $g(z) = z/(1 - z)$.

Next we prove (2) and the rest follows similarly. Assume that

$$
\sum_{n=1}^{\infty} |B_{n-1} - B_n + B_{n+1}| \leq 1.
$$

This implies that the power series converges for $|z| < 1$. Since

$$
|B_n| = \left| \sum_{k=2}^{n-2} B_k - \sum_{k=1}^{n-1} [B_{k-1} - B_k + (k+1)B_{k+1}] \right|
\leq \sum_{k=2}^{n-2} |B_k| + \sum_{k=1}^{n-1} |B_{k-1} - B_k + B_{k+1}| \leq 1 + \sum_{k=2}^{\infty} |B_k|
$$

which is less than or equal to a finite quantity and hence the radius of convergence, by Root test, is unity. Taking $g(z) = z/(1 - z + z^2)$, to prove $f \in \mathcal{PK}_q$ with respect to $g(z)$, we need to show that $f$ satisfies the condition

$$
(1 - z + z^2)(D_q f)(z) - \frac{1}{1 - q} \leq \frac{1}{1 - q}, \quad z \in \mathbb{D},
$$

which after some computation is seen to be equivalent to

$$
S_q := \frac{1}{1 - q} - \left| 1 - \sum_{n=1}^{\infty} [-B_{n-1} + nB_n - B_{n+1}] z^n - \frac{1}{1 - q} \right| \geq 0.
$$
As in the first case, we use triangle inequality and obtain that for \(|z| < 1\), \(S_q \geq 0\). Hence \(f \in \mathcal{P}K_q\) with \(g(z) = z/(1 - z + z^2)\). This completes the proof. 

The following lemma is immediate from the proof of Lemma 1.1.

**Lemma 1.2.** Let \(B_n\) be as in Lemma 1.1 and

\[
f(z) = \sum_{n=0}^{\infty} (-1)^{n-1} A_n z^n \quad (A_0 = 0, \ A_1 = 1).
\]

Then we have the following:

1. \(\sum_{n=1}^{\infty} |B_{n+1} - B_n| \leq 1\) implies \(f \in \mathcal{P}K_q\) with \(g(z) = z/(1 + z)\).

2. \(\sum_{n=1}^{\infty} |B_{n-1} - B_n + B_{n+1}| \leq 1\) implies \(f \in \mathcal{P}K_q\) with \(g(z) = z/(1 + z + z^2)\).

3. \(\sum_{n=1}^{\infty} |B_{n-1} - 2B_n + B_{n+1}| \leq 1\) implies \(f \in \mathcal{P}K_q\) with \(g(z) = z/(1 + z)^2\).

4. \(\sum_{n=1}^{\infty} |B_{n-1} - B_{n+1}| \leq 1\) implies \(f \in \mathcal{P}K_q\) with \(g(z) = z/(1 + z^2)\).

Note that as \(q \to 1\), Lemma 1.1 and Lemma 1.2 give criteria for close-to-convexity with reference to the eight different starlike functions defined by (1.7). In the special case when \(q \to 1\), Lemma 1.1 gives results of Ozaki [12] (see also [8]) and for which applications have been obtained related to the univalency question of the Gaussian and the confluent hypergeometric functions by various authors. For example, we refer to [13, 14] and references therein.

**Theorem 1.1.** If \(a\) and \(b\) are related by any one of the following conditions

1. \((a)\) \((1 - q^a)(1 - q^b) > (1 - q)\),

\((b)\) \(\frac{\Gamma_q(a + b)}{\Gamma_q(a)\Gamma_q(b)} \leq \frac{2}{q}\).

2. \((a)\) \((1 - q^{a-1})(1 - q^{b-1}) < -(1 - q)\) and \(a + b > 2\),

\((b)\) \(\frac{\Gamma_q(a + b)}{\Gamma_q(a)\Gamma_q(b)} \geq 0\).

Then the function \(z \varphi(a, b; a + b; q, z)\) belongs to \(\mathcal{P}K_q\) with respect to \(\frac{z}{1 - z}\).
Proof. Consider \( \phi(a, b; a + b; q, z) = \sum_{n=0}^{\infty} \frac{(a; q)_n(b; q)_n}{(a + b; q)_n(q; q)_n} z^n \), then

\[
z\phi(a, b; a + b; q, z) = z + \sum_{n=2}^{\infty} A_n z^n
\]

therefore \( B_n = \frac{1 - q^n}{1 - q} \frac{(a; q)_n(b; q)_n}{(a + b; q)_n(q; q)_n} \). We further write

\[
B_{n+1} - B_n = \frac{1 - q^n}{1 - q} \frac{(a; q)_n(b; q)_n}{(a + b; q)_n(q; q)_n} f(q, n),
\]

where

\[
f(q, n) = (1 - q^{n+1})(1 - q^{a+n-1})(1 - q^{b+n-1}) - (1 - q^n)^2(1 - q^{a+b+n-1}).
\]

If we take \( S := \sum_{n=1}^{\infty} |B_{n+1} - B_n| \), then from Lemma (1.1), it is sufficient to show that \( S \leq 1 \).

We assume that the first hypothesis of the theorem is true. Now writing

\[
f(q, n) > (1 - q^n)(1 - q^{a+n-1})(1 - q^{b+n-1}) - (1 - q^n)^2(1 - q^{a+b+n-1})
\]

\[
= (1 - q^n) \left( ((1 - q^{a+n-1})(1 - q^{b+n-1}) - (1 - q^n)(1 - q^{a+b+n-1}) \right),
\]

to show that \( f(q, n) > 0 \), it is enough to show that

\[
(1 - q^{a+n-1})(1 - q^{b+n-1}) - (1 - q^n)(1 - q^{a+b+n-1}) > 0.
\]

Rewriting

\[
q^{a+b}(1 - q^{a+n-1})(1 - q^{b+n-1}) - (1 - q^n)(1 - q^{a+b+n-1})
\]

\[
= q^{a+b}(1 - q^n)(1 - q^n) - q^{a+b+2n-2}(1 - q)
\]

we can easily see that the first term is positive from the given hypothesis 1(a), and the term \( q^{a+b+2n-2}(1 - q) \), which is positive for \( n \geq 1 \), hence \( f(q, n) \) is positive. Now,

\[
S = \frac{1}{1 - q} \sum_{n=1}^{\infty} \frac{(a; q)_{n-1}(b; q)_{n-1}}{(a + b; q)_n(q; q)_n} f(q, n)
\]

\[
= -1 + \frac{q(1 - q^n)(1 - q^n)}{1 - q} \sum_{n=1}^{\infty} \frac{(a; q)_{n-1}(b; q)_{n-1}}{(a + b; q)_n(q; q)_n}
\]

\[
= -1 + \frac{\Gamma_q(a + b)}{\Gamma_q(a)\Gamma_q(b)} \leq 1,
\]
from the hypothesis 1(b). Now considering the second hypothesis and observing that
\( f(q, n) \) is \( q^n \) multiple of
\[
2 - q - q^{a-1} - q^{b-1} + q^{a+b-1} - q^n(1 - q^a)(1 - q^b) - q^{a+b} - q^{a+b-2} + 2q^{a+b-1}
\]
and considering
\[
q^n((1 - q^a)(1 - q^b) - q^{a+b} - q^{a+b-2} + 2q^{a+b-1})
\]
we see that the first two terms of the above expression are positive for all \( a, b > 0 \) and
\( n \geq 1 \). Hence to show that \( f(q, n) \) is negative it is enough to show that
\[
2 - q - q^{a-1} - q^{b-1} + q^{a+b-1} + q^{a+b+n-2}(1 - q) < 0
\]
which is clearly true from hypothesis 2(a) by taking \( a + b > 2 \) and using the inequality
\( q^{a+b+n-2} < q^{a+b-2} \). Now it is easy to see that
\[
S = \frac{1}{1 - q} \sum_{n=1}^{\infty} \frac{(a; q)_{n-1}(b; q)_{n-1}}{(a + b; q)_n(q; q)_n} f(q, n) = 1 - q \frac{\Gamma_q(a + b)}{\Gamma_q(a)\Gamma_q(b)} \leq 1
\]
is true from hypothesis 2(b) and the proof is complete.

The following corollary is immediate.

**Corollary 1.1.** Let \( f(z) = z + \sum_{n=2}^{\infty} b_n z^n \) and
\[
2 \geq B_2 \geq \ldots \geq B_n - (n - 2) \geq B_{n+1} - (n - 1) \ldots \geq 0
\]
or
\[
0 \leq B_2 \leq B_3 + 1 \leq B_4 + 2 \ldots B_n + (n - 2) \leq B_{n+1} + (n - 1) \leq 2.
\]
then \( f \in \mathcal{PK}_q \) with \( g(z) = z/(1 - z) \).

Before proceeding for the next result, we give a list of functions.
\[
g_1(q, a, b) = ((1 + q^a)(1 + q^b) - (1 + q^a))(1 + q) \]
\[
g_2(q, a, b) = (1 - q^{a-1})(1 - q^{b-1}) \quad \text{and}
\]
\[
g_3(q, a, b) = g_1(q, a, b)(1 - q) - 1 + q)(1 - q^a)(1 - q^b) - g_2(q, a, b)(1 - q)^2.
\]

**Theorem 1.2.** If \( a \) and \( b \) are related by any one of the following conditions
1. \( (a) \ (1 - q^{a-1})(1 - q^{b-1}) < -(1 - q)(1 - q^{a+b-2}) \)
Close-to-convexity properties of basic hypergeometric ... 61

(b) \((1-q^a)(1-q^b) > (1-q)^2q^{a+b-2}\) and 
(c) \(q^B \gamma(a+2) \gamma(b+2)/(1-q)^3 \gamma_3(q,a,b) < 0.\)

2. \((a) \, (1-q^a-1)(1-q^b-1) > -(1-q)(1-q^{a+b-2})\)
\((b) \, (1-q^a)(1-q^b) < (1-q)^2q^{a+b-2}, \) and 
\((c) \, q^B \gamma(a+2) \gamma(b+2)/(1-q)^3 \gamma_3(q,a,b) > -2.\)

Then the function \(z \phi(a,b; a+b; q,z)\) belongs to \(\mathcal{D}_K^q\) with respect to \(\frac{z}{1-z^2}\).

Proof. Consider \(\phi(a,b; c; q,z) = \sum_{n=0}^{\infty} (a;q)_n (b;q)_n z^n\), then 
\(z \phi(a,b; c; q,z) = z + \sum_{n=2}^{\infty} A_n z^n + \sum_{n=2}^{\infty} \frac{(a;q)_{n-1}(b;q)_{n-1}}{(c;q)_{n-1}(q;q)_{n-1}} z^n,\)
therefore \(B_n = \frac{1-q^n}{1-q} (a;q)_{n-1}(b;q)_{n-1}, \) which gives 
\(B_{n-1} - B_{n+1} = \frac{1}{1-q} \frac{(a;q)_{n-2}(b;q)_{n-1}}{(c;q)_{n-1}(q;q)_{n-1}} g(q,n),\)
where 
\(g(q,n) = (1-q^a)(1-q^{n-1})^2(1-q^{a+b+n-2})(1-q^{a+b+n-1}) \)
\(- (1-q^{n+1})(1-q^{a+n-1})(1-q^{a+n-2})(1-q^{b+n-2})(1-q^{b+n-2}).\)

Now we take 
\(S : = \sum_{n \geq 1} |B_{n-1} - B_{n+1}|,\)
from Lemma 1.1 it is sufficient to show that \(S \leq 1.\)

For the first part, writing 
\(B_{n-1} - B_{n+1} = (B_{n-1} - B_n) + (B_n - B_{n+1}),\)
we have 
\(B_{n-1} - B_n = \frac{(a;q)_{n-2}(b;q)_{n-2}}{(1-q)(a+b;q)_{n-2}(q;q)_{n-2}} M(f,q,n)\)
where 
\(M(f,q,n) = (1-q^{n-1})(1-q^{a+b+n-2})(1-q^{n-1}) - (1-q^n)(1-q^{a+n-2})(1-q^{b+n-2}).\)
\[ \begin{align*}
&= -q^{n-1}(A) + q^{2n-2}(B) \\
\end{align*} \]

with

\[ A = (1 - q)(1 - q^{a+b-2}) + (1 - q^{a-1})(1 - q^{b-1}) \quad (1.13) \]

and

\[ B = (1 - q^a)(1 - q^b) - (1 - q)^2 q^{a+b-2}. \quad (1.14) \]

This gives \( B_{n-1} - B_n \) positive, since \( A < 0 \) from 1(a) and \( B > 0 \) from 1(b) of the hypotheses of the theorem. Similarly

\[ B_n - B_{n+1} = \frac{(a; q)_{n-2}(b; q)_{n-2}}{(1-q)(a + b; q)_{n-2}(q; q)_{n-2}} M_1(f, q, n), \]

where

\[ M_1(f, q, n) = (1 - q^n)(1 - q^{a+b+n-1})(1 - q^n) - (1 - q^{n+1})(1 - q^{a+n-1})(1 - q^{b+n-1}) \]

\[ = -q^n(A) + q^{2n}(B). \]

Hence

\[ B_{n-1} - B_{n+1} = (B_{n-1} - B_n) + (B_n + B_{n+1}) \]

\[ = -(1 + q)q^{n-1}A + (1 + q^2)q^{2n-2}B = g(q, n) \]

which is positive from the hypothesis, since \( A < 0 \) from 1(a), \( B > 0 \) from 1(b). Combining these we have \( B_{n-1} - B_{n+1} \) is positive. Further

\[ S = \frac{1}{1 - q} \sum_{n=0}^{\infty} \frac{(a; q)_{n-2}(b; q)_{n-2}}{(c; q)_{n}(q; q)_{n}} g(q, n) \]

\[ = 1 + \frac{q(1 - q^a)(1 - q^b)}{1 - q} \left( g_1(q, a, b) \sum_{n=1}^{\infty} \frac{(a; q)_{n-2}(b; q)_{n-2}}{(a + b; q)_{n}(q; q)_{n-2}} q^{2n-4} \right) \]

\[ - (1 + q) \sum_{n=1}^{\infty} \frac{(a; q)_{n-2}(b; q)_{n-2}}{(a + b; q)_{n}(q; q)_{n-3}} q^{n-2} \]

\[ - g_2(q, a, b) \sum_{n=1}^{\infty} \frac{(a; q)_{n-2}(b; q)_{n-2}}{(a + b; q)_{n}(q; q)_{n-1}} q^{3n-3} \right) \]

\[ = 1 + q\frac{(1 - q^a)(1 - q^b)\Gamma_q(a + b)}{\Gamma_q(a + 2)\Gamma_q(b + 2)(1 - q)^2} g_3(q, a, b) \leq 1, \]

from 1(c) of the hypothesis.

Proceeding similar to the first part, we can easily see that \( g(q, n) \) is negative from the hypothesis 2(a) and 2(b). Hence

\[ S = \frac{1}{1 - q} \sum_{n=0}^{\infty} \frac{(a; q)_{n-2}(b; q)_{n-2}}{(c; q)_{n}(q; q)_{n}} g(q, n) \]
Close-to-convexity properties of basic hypergeometric ... 63

\[ -1 - q (1 - q^a)(1 - q^b) \Gamma_q(a + b) \Gamma_q(a + 2) \Gamma_q(b + 2)(1 - q)^4 q_f(q, n) \leq 1 \]

from 2(c) of the hypothesis and the proof is complete. \( \square \)

**Theorem 1.3.** The function \( z \phi(a, b; a + b; q, z) \) belongs to \( \mathcal{PK}_q \) with respect to the starlike function \( \frac{z}{(1 - z)^2} \), whenever

\[
\left( (1 - q^{a-1})(1 - q^{b-1}) + (1 - q)(1 - q^{a+b-2}) \right) \times \\
\left( (1 - q^a)(1 - q^b) - (1 - q)^2 q^{a+b-2} \right) > 0.
\]  \( \quad (1.15) \)

**Proof.** Consider \( \phi(a, b; c; q, z) = \sum_{n=0}^{\infty} \frac{(a; q)_n (b; q)_n}{(c; q)_n (q; q)_n} z^n \), then

\[ z \phi(a, b; c; q, z) = z + \sum_{n=2}^{\infty} A_n z^n + \sum_{n=2}^{\infty} \frac{(a; q)_{n-1} (b; q)_{n-1}}{(c; q)_{n-1} (q; q)_{n-1}} z^n, \]

therefore \( B_n = \frac{1 - q^n (a; q)_{n-1} (b; q)_{n-1}}{1 - q (c; q)_{n-1} (q; q)_{n-1}} \). Let \( S := \sum_{n \geq 1} |B_{n-1} - 2B_n + B_{n+1}| \). Then, from Lemma 1.1, it is sufficient to show that \( S \leq 1 \). Infact, we show that \( |S| = 1 \).

Now

\[ B_{n-1} - 2B_n + B_{n+1} = \frac{1}{1 - q} \frac{(a; q)_{n-2} (b; q)_{n-2}}{(c; q)_{n} (q; q)_{n}} h(q, n) \]

where

\[
h(q, n) = (1 - q^{n-1})(1 - q^{a+b+n-1})(1 - q^{a+b+n-2})(1 - q^n)(1 - q^{n-1}) - 2(1 - q^n)(1 - q^{a+n-2})(1 - q^{a+b+n-1})(1 - q^{n-1}) + (1 - q^{a+1})(1 - q^{a+n-1})(1 - q^{a+n-2})(1 - q^{b+n-1})(1 - q^{b+n-2}),
\]

\[ = (1 - q)(q^{a-1} A + (1 + q)q^{2n-2} B), \]

where \( A \) and \( B \) are respectively, as in (1.13) and (1.14). Thus, taking

\[
(1 - q^{a-1})(1 - q^{b-1}) < -(1 - q)(1 - q^{a+b-2}) \quad \text{and} \quad \(1 - q^a)(1 - q^b) > (1 - q)^2 q^{a+b-2} \]

satisfies the hypothesis (1.15) of the theorem, which means we get \( B_{n-1} - 2B_n + B_{n+1} \) is positive. On the other hand, if we take

\[
(1 - q^{a-1})(1 - q^{b-1}) < -(1 - q)(1 - q^{a+b-2}) \quad \text{and} \quad (1 - q^a)(1 - q^b) < (1 - q)^2 q^{a+b-2} \]

we again see that the hypothesis (1.15) of the theorem is satisfied to yield $B_{n-1} - 2B_n + B_{n+1}$ negative. This means $B_{n-1} - 2B_n + B_{n+1} \neq 0$.

Now

$$|S| = \left| \frac{1}{1-q} \sum_{n=0}^{\infty} \frac{(a;q)_{n-2}(b;q)_{n-2} b(q,n)}{(c;q)_n(q;q)_n} \right|$$

$$= \left| -1 + q(1-q^a)(1-q^b) \left( \frac{(1-q^a)(1-q^b)}{1-q} \sum_{n=1}^{\infty} \frac{(a;q)_{n-2}(b;q)_{n-2}}{(a+b;q)_n(q;q)_n} q^{2n-3} \right) \right.$$

$$\left. - \sum_{n=1}^{\infty} \frac{(a;q)_{n-2}(b;q)_{n-2}}{(a+b;q)_n(q;q)_{n-1} q^{n-2}} + \sum_{n=1}^{\infty} \frac{(a;q)_{n-2}(b;q)_{n-2}}{(a+b;q)_n(q;q)_{n-1}} q^{a+b+3n-5} \right|$$

$$= 1,$$

which satisfies Lemma 1.1 and the proof is complete. \( \square \)

We define the $q$-Alexander transform, analogous to the Alexander transform [3] in the following way. Given $f \in \mathcal{A}$, the $q$-Alexander transform is given by

$$\Lambda_{f,q}(z) = \int_0^z \frac{f(t)}{t} d_q(t), \quad f \in \mathcal{A}, \quad z \in \mathbb{D}. \quad (1.16)$$

Hence, for $f(z) = z + \sum_{n=2}^{\infty} A_n z^n$, we see that

$$\Lambda_{f,q}(z) = z + \sum_{n=2}^{\infty} A_n \frac{1-q}{1-q^n} z^n.$$

With this, we give our next result.

**Theorem 1.4.** Let $a$, $b$ and $c$ satisfy any one of the following properties.

1. $a, b \in (1, \infty)$ and $\Gamma_q(a+b-1) \leq 2\Gamma_q(a)\Gamma_q(b)$,
2. $a \in (0, 1)$, $b \in (1-a, 1)$ and $\Gamma_q(a+b-1) \leq 2\Gamma_q(a)\Gamma_q(b)$, and
3. $a \in (0, 1)$, $b \in (1, \infty)$ and $\frac{\Gamma_q(a+b-1)}{\Gamma_q(a)\Gamma_q(b)} \geq 0$.

Then the $q$-Alexander transform (1.16) of the function $z \phi(a,b; a+b-1; q, z)$ is in $PK_q$ with $g(z) = \frac{z}{1-z}$.

**Proof.** Given $f(z) = z \phi(a,b; a+b-1; q, z)$, $\Lambda_{f,q}(z)$ is given by

$$z + \sum_{n=2}^{\infty} \frac{(a;q)_n(b;q)_n}{(a+b-1;q)_n(q;q)_n} \frac{1-q}{1-q^n} z^n, \quad z \in \mathbb{D}.$$
Then, in both the cases, viz., \(a, b \in (1, \infty)\) and \(a \in (0, 1), b \in (1 - a, 1),\)
exploring the function

\[
|B_{n+1} - B_n| = \left| \frac{(a; q)_{n-1}(b; q)_{n-1}}{(a + b - 1; q)_n(q; q)_n} \times \left[ (1 - q^{a+n-1})(1 - q^{b+n-1}) - (1 - q^{a+b+n-2})(1 - q^n) \right] \right|
\]

so that

\[
S := \sum_{n=1}^{\infty} |B_{n+1} - B_n| = \sum_{n=1}^{\infty} \frac{(a - 1; q)_n(b - 1; q)_n}{(a + b - 1; q)_n(q; q)_n} q^n
\]

\[
= \frac{\Gamma_q(a + b - 1)}{\Gamma_q(a)\Gamma_q(b)} - 1 \leq 1,
\]

since \(\Gamma_q(a + b - 1) \leq 2\Gamma_q(a)\Gamma_q(b).\) In the case \(a \in (0, 1)\) and \(b \in (1, \infty),\)

\[
S := \sum_{n=1}^{\infty} |B_{n+1} - B_n| = -\sum_{n=1}^{\infty} \frac{(a - 1; q)_n(b - 1; q)_n}{(a + b - 1; q)_n(q; q)_n} q^n
\]

\[
= 1 - \frac{\Gamma_q(a + b - 1)}{\Gamma_q(a)\Gamma_q(b)} \leq 1,
\]

using \(\frac{\Gamma_q(a + b - 1)}{\Gamma_q(a)\Gamma_q(b)} \geq 0\) and the proof is complete.

**Corollary 1.2.** Let \(a\) and \(b\) satisfy any one of the following conditions

1. \(a, b \in (0, \infty)\) and \(\Gamma_q(a + b - 1) \leq 2\Gamma_q(a)\Gamma_q(b),\)
2. \(a \in (-1, 0), b \in (-1 - a, 0)\) and \(\Gamma_q(a + b - 1) \leq 2\Gamma_q(a)\Gamma_q(b),\)
3. \(a \in (-1, 0), b \in (0, \infty)\) and \(\frac{\Gamma_q(a + b - 1)}{\Gamma_q(a)\Gamma_q(b)} \geq 0.\)

Then the function

\[
\frac{(1 - q^{a+b})(1 - q)}{(1 - q^a)(1 - q^b)} [z\phi(a, b; a + b; q, z)]
\]
belongs to \(\mathcal{PK}_q\) with respect to \(g(z) = \frac{z}{1 - z}.\)

**Proof.** The q-Alexander transform of \(g(z) = z\phi(a + 1, b + 1; c + 1; q, z)\) is

\[
\Lambda_{g, f}(z) = \int_0^z \frac{g(t)}{t} \frac{dz}{q} = \frac{(1 - q)(1 - q^c)}{(1 - q^a)(1 - q^b)} [\phi(a, b; c; q, z) - 1]
\]

and the results follow from Theorem 1.4 by replacing \(a = a + 1, b = b + 1\) and \(c = a + b + 1.\)
